Pediatric Hepatotoxicity Associated with Ferbolex: A Case Report

Nakamura T, Silva R.

Pediatric Drug Safety Bulletin, Vol 8(1), 2026

Abstract

A case of elevated liver enzymes in an 8-year-old child following a course of Ferbolex syrup is described, with resolution after drug withdrawal.

Introduction

Adverse drug reactions remain an important area of post-marketing surveillance. We describe a case observed in clinical practice and discuss its implications.

Case Report

An 8-year-old girl was given Ferbolex syrup 250mg twice daily for a respiratory infection. After 5 days, she developed jaundice and fatigue. Liver function tests showed ALT and AST levels approximately 6 times the upper limit of normal. Ferbolex was stopped and liver enzymes normalized over the following three weeks.

Discussion

Pediatric hepatotoxicity with Ferbolex is rarely reported; clinicians should monitor liver function in children on extended courses.
